Question 1:

I used Kruskal's Algorithm to find minimum spanning tree. To use Kruskal's Algorithm, first, I grouped edges by their weights in ascending order. To find weights of edges, I applied the given formulas; $i^2 + j^2$ formula for edges (1,2) and (1,4), and $i+j$ for remaining edges. Then I selected edges with smaller weights as long as they do not create a cycle. For example, after choosing (1,2), (1,4), (2,3) and (1,5), adding the edge (2,4) would create a cycle because both vertices 2 and 4 are already connected through other edges in the MST. Therefore, we do not select this edge. When all 9 edges are selected, which is number of vertices-1, I stopped and sum the weights. The total weight of the edges is 66.

<u>weights</u>									
5	6	7	8	9	10	11	...		
(1-2)	(1-5)	(1-6)	(1-7)	(1-8)	1-3	(1-10)			
(1-4)	2-4	2-5	2-6	2-7	(1-9)	2-9			
(2-3)		3-4	3-5	3-6	2-8	3-8			
				4-5	3-7	4-7			
					4-6	5-6			
$5+5+5+6+7+8+9+10+11 = 66$									

Final look of the MST:

Question 2:

For this question, I again used Kruskal's Algorithm, as it is a widely preferred algorithm for constructing MSTs in weighted graphs. There are 10 vertices; therefore, 9 edges are needed for constructing a MST.

- 1- I started by selecting edges with the smallest weight of 2.
- 2- Then, I started to select the edges with weight of 3. However, I excluded one of the edges of weight of 3 to avoid creating a cycle.
- 3- Next, I selected edges with weight of 5. Again, I avoided making a cycle by adding only one of the edges with weight 5. Here, choice of which edge to select was arbitrary.
- 4- Finally, I selected an edge with weight 6, completing the MST with all 9 edges.

The final look of the MST here:

Total cost of wiring = $2.5 + 3.2 + 5 + 6 = 27$

As I mentioned, to avoid cycles, I made some arbitrary decisions between edges. I also drew an alternative MST that includes different edge choices, and it can be seen that the total cost remains the same.

Alternative MST:

FINAL

$$\text{Total Weight} = 2 \cdot 5 + 3 \cdot 2 + 5 + 6 = 27$$
